

Wiselib School 2010

Session 4

Insight into Wiselib Internals

Tobias Baumgartner

Institute of Operating Systems and Computer Networks
Handout on <http://www.ibr.cs.tu-bs.de/alg/winterschool/>

October 2010

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Wiselib Algorithm Integration

- Two options for Wiselib Algorithm Integration
 - **Generic Wiselib Application**
⇒ Compile the same application for several platforms
 - **Direct Integration**
⇒ Use Wiselib algorithms directly on your platform

Generic Wiselib Application

- Already known from hands-on task
- Write code **once**, run on **different** platforms
→ Change make target (shawn, isense, contiki_sky, scw_msb, ...)
- **Advantages**
 - Totally flexible, especially for **debugging**
⇒ **Test** code on different platforms
 - **Easy** to start with
 - Very nice for **new platform** integration
- **Disadvantages**
 - **Bound to** generic application
 - **No direct access** to operating system
 - Limited when trying to pass **different facet** implementations
 - Restrictions like in several **middleware** approaches

The Wiselib is an **algorithm library**, no middleware

Direct Integration

- Directly use a Wiselib algorithm in your OS/firmware
- **Disadvantages**
 - Algorithm integration needed to be done for **each platform**
 - **Tedious** work for **testing** on different platforms
 - **Perhaps hard** for new platform support
 - ⇒ Makefile adaptation, C++ compiler for own firmware, ...
- **Advantages**
 - Full **flexibility** in hardware/OS access
 - Do **not bind** the application developer to anything
 - Existing systems **not affected**, but **extendable**
 - **Still possible** to develop **heterogeneous** systems
 - ⇒ When **TinyOs** can communicate with **Contiki**, they can also run a **common Wiselib algorithm**

Main design goal of the Wiselib

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Generic Wiselib Application Revisited

- Separate application with init method

```
1 class MyGenericApplication {
2     public:
3         void init( Os::AppMainParameter& value )
4         {
5             radio_ = &wiselib::FacetProvider<Os, Os::Radio>::get_facet( value );
6         };
7
8         Os::Radio::self_pointer_t radio_;
9 }
```

- Create Wiselib Application

```
10 wiselib::WiselibApplication<Os, MyGenericApplication> my_app;
```

- Implement `application_main()`, call `init`

```
11 void application_main( Os::AppMainParameter& value )
12 {
13     my_app.init( value );
14 }
```

Wiselib Application Template

- Definition

```
1 wiselib::WiselibApplication<Os, MyGenericApplication> my_app;
```

- Global Variable

- Only **one** instance
- Constructor is called before system initialization (before `main()`)

- Given facts for supported systems

- No dynamic memory support on Contiki, SCW, TinyOs by default
- Shawn has usually more processors
 - ⇒ Multiple instances of `MyGenericApplication` needed

Default Wiselib Application

```
1  template<typename OsModel_P ,
2          typename Application_P>
3  class WiselibApplication
4  {
5  public:
6      typedef OsModel_P OsModel;
7      typedef Application_P Application;
8      typedef typename OsModel::AppMainParameter AppMainParameter;
9
10     void init( AppMainParameter& os )
11     {
12         application_.init( os );
13     };
14
15 private:
16     Application application_;
17 };
```

- No constructor
- Private member of passed Application_P (template parameter)
- Only **one** instance of application
- Call to `init(...)` is *forwarded*

Shawn Wiselib Application

```
1  template<typename Application_P>
2  class WiselibApplication<ShawnOsModel, Application_P>
3  {
4  public:
5      typedef ShawnOsModel OsModel;
6      typedef Application_P Application;
7
8      void init( ShawnOs& os )
9      {
10         Application *app = new Application();
11         app->init( os );
12     };
13 }
```

- Template specialization of WiselibApplication for Shawn
- No constructor
- No private member
- Create a **new** application **instance** per call
- Initialize newly created application

Outline

- ① Application Development
- ② Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information**
 - Whys and Wherefores of the Facet Provider
- ③ Direct Integration: Using the Knowledge of your Platform
- ④ Delegates: Flexible Method Pointers for Callbacks
- ⑤ Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

The AppMainParameter

- Passed in `application_main()`

```
1 void application_main( Os::AppMainParameter& value )  
2 {  
3     my_app.init( value );  
4 }
```

- System specific information
- Defined by `OsModel`
 - Processor in Shawn
 - `isense::Os` in `iSense`
 - Not needed in Contiki: Dummy parameter

Calling `application_main()` in iSense

```
1  class iSenseWiselibApplication: public isense::Application
2  {
3      public:
4          iSenseWiselibApplication( isense::Os &os)
5              : isense::Application( os ),
6                os_( os )
7          {}
8
9          virtual void boot ( void )
10         { application_main( os_ ); }
11
12         isense::Os &os_;
13     }
```

- Internally, an ordinary iSense application
- Call `application_main` (the one in Generic Wiselib Application)
- Inside `application_main`:
 - Initialize Generic Wiselib Application

Calling `application_main()` in Shawn

```
1  void
2  WiselibShawnStandaloneProcessor::
3  boot( void )
4      throw()
5  {
6      os_.proc = this;
7      application_main( os_ );
8  }
```

- Internally, an ordinary Shawn processor
- Set pointer to processor, then pass to `application_main`
- Inside `application_main`:
 - Initialize Generic Wiselib Application

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Generic Wiselib Application

- Facet instantiation

```
1 radio_ = &wiselib::FacetProvider<Os, Os::Radio>::get_facet( value );  
2 ...  
3 Os::Radio::self_pointer_t radio_;
```

- Different requirements for different systems

- Shawn: Create one radio per processor
- iSense: Create one radio that has access to iSense Os pointer
- Contiki: Create one radio that only calls C funtions

- Solution (again): Template Specialization

- Generic facet provider
- Specialization for sytems with specific needs

Generic Facet Provider

```
1  template<typename OsModel_P ,  
2          typename Facet_P>  
3  class FacetProvider  
4  {  
5  public:  
6      typedef OsModel_P OsModel;  
7      typedef Facet_P Facet;  
8      typedef typename OsModel::AppMainParameter AppMainParameter;  
9  
10     static Facet& get_facet( AppMainParameter& os )  
11     { return facet_; };  
12  
13 private:  
14     static Facet facet_;  
15 };
```

- Static data member
- Only **one** facet instance
- Only default constructor used

Example: Contiki Timer Model

```
1  template<typename OsModel_P>
2  class ContikiTimerModel
3  {
4  public:
5      typedef OsModel_P OsModel;
6
7      typedef ContikiTimerModel<OsModel> self_type;
8      typedef self_type* self_pointer_t;
9
10     typedef uint32_t millis_t;
11
12     template<typename T, void (T::* TMethod)(void*)>
13     int set_timer( millis_t millis, T *obj_pnt, void *userdata )
14     {
15         // only C function calls!
16     }
17 };
```

- No constructor
- Only function calls in timer used

iSense Facet Provider

```
1  template<typename Facet_P>
2  class FacetProvider<iSenseOsModel , Facet_P>
3  {
4  public:
5      typedef iSenseOsModel OsModel;
6      typedef Facet_P Facet;
7
8      static Facet& get_facet( isense::Os& os )
9      {
10         if ( facet_ == 0 )
11             facet_ = new Facet(os);
12
13         return *facet_;
14     }
15
16 private:
17     static Facet *facet_;
18 };
```

- Template Specialization: **Only** used for iSense
- Static data member: Pointer!
- Only **one** instance per facet
- Create new instance when calling get_facet()
- Pass isense::Os in constructor

Example: iSense Radio Model

```
1  template<typename OsModel_P>
2  class iSenseRadioModel
3      : public isense::Receiver
4  {
5      iSenseRadioModel( isense::Os& os )
6          : os_(os)
7      {
8          os_.dispatcher().add_receiver( this );
9      }
10
11     int send( node_id_t id, size_t len, block_data_t *data )
12     {
13         os_.radio().send( id, len, data, 0, 0 );
14         ...
15     }
16
17     isense::Os& os_;
```

- `isense::Os` passed in constructor
- `isense::Os` can be used within the whole model
- Possible, because we **know** how the facet provider looks like

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Integration in Native Applications

- Developer knows the Os Facets for the platform
- **Not needed**
 - Facet provider
 - Wiselib Application
 - `application_main(...)`
 - `Os::AppMainParameter`
- **Instead**
 - Use the knowledge of your platform
 - Create facets directly (as required for the corresponding platform)
 - `Os::AppMainParameter` is known

Example: iSense Integration (1 of 2)

- Directly include Os Facets

```
1#include "external_interface/isense/isense_os.h"
2#include "external_interface/isense/isense_radio.h"
3...
4#include "algorithms/routing/dsdv/tree_routing.h"
```

- When declare typedefs, use knowledge of OsModel

```
1typedef wiselib::iSenseOsModel Os;
2typedef wiselib::TreeRouting<Os, Os::Timer, Os::Radio> tree_routing_t;
```

- Define needed data members and methods

```
1class iSenseDemoApplication
2{
3    void receive_routing_message (uint16 src_addr, uint8 len, uint8 *buf) ;
4    ...
5    Os::Radio radio_;
6    Os::Timer timer_;
7    Os::Debug debug_;
8    tree_routing_t routing_;
```

Example: iSense Integration (2 of 2)

- Pass in `isense::Os` in constructor to facets

```
1 iSenseDemoApplication::
2 iSenseDemoApplication(isense::Os& os)
3     : isense::Application(os),
4       radio_( os ),
5       timer_( os ),
6       debug_( os )
7 {}
```

- In `boot()`, init routing and register callback

```
1 void iSenseDemoApplication::boot(void) {
2     routing_.init( radio_, timer_, debug_ );
3     routing_.enable_radio();
4     routing_.reg_recv_callback<
5         iSenseDemoApplication,
6         &iSenseDemoApplication::receive_routing_message>(this);
7 }
```

- Receive messages in `iSense`, which were sent over Wiselib algorithm

```
1 void
2 iSenseDemoApplication::
3 receive_routing_message (uint16 src_addr, uint8 len, uint8 *buf)
4 {
5     os_.debug("received routing message from %i", src_addr);
6 }
```

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks**
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Design Issues for Callback Structure

- Ability to register callback (method pointer) in another class
- Requirements
 - Flexible
 - Fast
 - Small (in code space)
- **Our Solution:** Delegates
- Known from C#

```
1 public delegate int DelegateToMethod(int x, int y);  
2  
3 public static int Add(int first, int second)  
4 { return first + second; }  
5  
6 DelegateToMethod aDelegate = new DelegateToMethod(Math.Add);  
7 Console.WriteLine(aDelegate(5,5));
```

- With C++ and Templates
 - We use the approach of Sergey Ryazanov
 - www.codeproject.com/KB/cpp/ImpossiblyFastCppDelegate.aspx

Delegates: Internals (1 of 2)

- Basic class delegate
 - Object pointer of type void
 - Stub pointer that points to a static template function (here: return type void, expect parameter of type int)

```
1 class delegate
2 {
3     ...
4     typedef void (*stub_type)(void* object_ptr, int);
5
6     void* object_ptr;
7     stub_type stub_ptr;
8     ...
9 };
```

- Meaning of pointers
 - Object pointer: Pointer to *callbacked* class with member function
 - Stub pointer: Call the member function of the object pointer:

```
1 template <class T, void (T::* TMethod)(int)>
2 static void method_stub(void* object_ptr, int a1)
3 {
4     T* p = static_cast<T*>(object_ptr);
5     return (p->*TMethod)(a1);
6 }
```

Delegates: Internals (2 of 2)

- Stub pointer is created via static member function `from_method` of the delegate class

```
1 template <class T, void (T::* TMethod)(int)>
2 static delegate from_method(T* object_ptr)
3 {
4     delegate d;
5     d.object_ptr = object_ptr;
6     d.stub_ptr = &method_stub<T, TMethod>;
7
8     return d;
9 }
```

- Finally: Invocation of a delegate

```
1 void operator()(int a1) const
2 {
3     return (*stub_ptr)(object_ptr, a1);
4 }
```

Delegates: Users' view

- Internals hidden by Wiselib
- Example: Callback in radio

```
1 #include "util/delegates/delegate.hpp"
2
3 typedef delegate3<void, node_id_t, size_t, block_data_t*> radio_delegate_t;
4 radio_delegate_t cb_;
5
6 template<class T, void (T::*TMethod)(node_id_t, size_t, block_data_t*)>
7 int
8 reg_rcv_callback( T *obj_pnt )
9 {
10     cb_ = radio_delegate_t::from_method<T, TMethod>( obj_pnt );
11 }
12
13 void on_receive(...)
14 {
15     if (cb_)
16         cb_( from, len, buf );
17 }
```

- Callback registration

```
1 radio_ -> reg_rcv_callback<MyApp, &MyApp::rcv_radio_message>(this);
```

Os Facets: Overview

	OS	Radio (TX Power Ext.) (RSSI/LQI Ext.)	Timer	Logging	Clock (Set Clock Ext.)	Serial Comm.	Position	
WP2 OSA	⊕	○	○	⊕				4/7
Contiki	⊕	○	⊕	⊕		○		5/7
TinyOS	⊕			⊕				2/7
iSense	⊕	⊕ ● ●	⊕	⊕	⊕ ●	⊕	○	7/7
ScatterWeb	⊕	○	⊕	⊕				4/7
Shawn	⊕	⊕ ● ●	⊕	⊕	⊕		⊕	6/7

(⊕ = fully supported, ○ = works / proof of concept, ● = with extension)

Example: Contiki Timer

Example: Contiki Timer (1 of 2)

- Timer item that is used for Contiki etimer

```
1 typedef delegate1<void, void*> contiki_timer_delegate_t;
2
3 struct timer_item
4 {
5     struct timer_item *next;
6     struct etimer etimer;
7     struct process *p;
8     contiki_timer_delegate_t cb;
9     void *ptr;
10 };
```

- set_timer implementation

```
1 template<typename T, void (T::* TMethod)(void*)>
2 set_timer( millis_t millis, T *obj_pnt, void *userdata )
3 {
4     uint16_t secs = millis >> 10;
5
6     timer_item *item = get_timer_item_ref();
7     item->p = PROCESS_CURRENT();
8     item->cb = contiki_timer_delegate_t::from_method<T, TMethod>( obj_pnt );
9     item->ptr = userdata;
10
11     PROCESS_CONTEXT_BEGIN( &timer_process );
12     etimer_set( &item->etimer, CLOCK_SECOND * secs );
13     PROCESS_CONTEXT_END( &timer_process );
14     return SUCCESS;
15 }
```

Example: Contiki Timer (2 of 2)

- Contiki internal timer

```
1  PROCESS( timer_process , "timer process" );
2  PROCESS_THREAD( timer_process , ev , data )
3  {
4      PROCESS_BEGIN();
5
6      while (1)
7      {
8          PROCESS_YIELD_UNTIL( ev == PROCESS_EVENT_TIMER );
9          for ( int i = 0; i < MAX_REGISTERED_TIMER; i++ )
10             {
11                 struct timer_item *c = &timer_items[i];
12                 if ( &c->etimer == data )
13                     {
14                         PROCESS_CONTEXT_BEGIN( c->p );
15                         if ( c->cb )
16                             c->cb( c->ptr );
17                         PROCESS_CONTEXT_END( c->p );
18                         c->cb = contiki_timer_delegate_t();
19                         break;
20                     }
21             }
22     }
23
24     PROCESS_END();
25 }
```

Example: iSense Radio

Example: iSense radio

- iSense Radio: Direct calls to `isense::Os`

```
1 template<typename OsModel_P>
2 class iSenseRadioModel
3     : public isense::Receiver
4 {
5 public:
6     typedef OsModel_P OsModel;
7     ...
8     iSenseRadioModel( isense::Os& os )
9         : os_(os)
10 { os_.dispatcher().add_receiver( this ); }
11
12 int send( node_id_t id, size_t len, block_data_t *data )
13 { os_.radio().send( id, len, data, 0, 0 ); return SUCCESS; }
14
15 int enable_radio()
16 { os_.radio().enable(); return SUCCESS; }
17
18 int disable_radio()
19 { os_.radio().disable(); return SUCCESS; }
20
21 node_id_t id()
22 { return os_.id(); }
```

Outline

- 1 Application Development
- 2 Basics of the Generic Wiselib Application
 - The Wiselib Application Template
 - The AppMainParameter: Hiding system specific information
 - Whys and Wherefores of the Facet Provider
- 3 Direct Integration: Using the Knowledge of your Platform
- 4 Delegates: Flexible Method Pointers for Callbacks
- 5 Porting the Wiselib to a new Platform
 - Os Facets Revisited
 - Essentials for new Platform Support

Porting to a new Platform

- Facet selection
 - OsModel: Provide basic data types (0 methods)
 - Radio: Send messages (6 methods)
 - Timer: Register timed callbacks (1 method)
 - Debug: Write out text messages (1 method)

⇒ Basic algorithms can be started

⇒ **Only 8** methods to implement

- Makefile support
 - Generic Wiselib Application
 - Provide call to `application_main()`
 - Link application to firmware
 - Direct integration
 - Compile application with C++ compiler
 - In case of need, use `extern "C"`

Example: Contiki Makefile for Generic Wiselib Application

Generic Wiselib Application: Contiki Example

```
1 export CONTIKI=$(CONTIKI_PATH)
2 include $(CONTIKI_PATH)/Makefile.include
3
4 CXXFLAGS += ...
5 LDFLAGS += -L. -L$(WISELIB_BASE)/applications/lib \
6 $(OBJECTDIR)/contiki-$(TARGET)-main.o \
7 contiki-$(TARGET).a
8
9 contiki.msp: $(PROJECT_OBJECTFILES) $(PROJECT_LIBRARIES) contiki-$(TARGET).a
10 @echo "compiling..."
11 msp430-g++ $(CXXFLAGS) -o out/contiki_os.o \
12 -c $(WISELIB_PATH)/external_interface/contiki/contiki_os.cpp
13 msp430-g++ $(CXXFLAGS) -o out/contiki_timer.o \
14 -c $(WISELIB_PATH)/external_interface/contiki/contiki_timer.cpp
15 ...
16 @echo "linking..."
17 msp430-g++ $(LDFLAGS) -o out/$(BIN_OUT).elf out/$(BIN_OUT).o \
18 out/contiki_os.o out/contiki_timer.o out/contiki_radio.o \
19 out/contiki_uart.o
20 @echo "make hex..."
21 msp430-objcopy -O ihex out/$(BIN_OUT).elf out/$(BIN_OUT).hex
22 msp430-objcopy -O binary out/$(BIN_OUT).elf out/$(BIN_OUT).bin
```

- Generate Contiki library
- Compile own code with C++-Compiler, then link Contiki

Example: Direct Integration on iSense

Direct Integration: iSense Example

- Add Wiselib include directories to iSense Makefile

Thoughts: Direct Integration in Contiki

Direct Integration: Contiki

- This is a little bit more tricky...
- Not done (**yet!**)
- How it would work in principle
 - Influence make process
 - Compile firmware with C-Compiler
 - In main application, embed all Contiki includes in `extern "C"`
 - Compile main application with C++ compiler

Thanks
