- Basics on probability theory
- Randomised search approaches
- Cooperative transmission schemes
- Distributed adaptive beamforming
- Feedback based approaches
- Asymptotic bounds on the synchronisation time
- Alternative algorithmic approaches
- Alternative Optimisation environments
- An adaptive communication protocol

## Outline

## Basics of probability theory

(1) Introduction
(2) Notation
(3) Calculation with probabilities
(4) The Markov inequality
(5) The Chernoff bound

## Probability in everyday life

We are confronted with Probability constantly:

- Weather forecasts
- Quiz shows
- ...

## Example

## The treasure behind the doors

## Example

## The treasure behind the doors

## Example

## The treasure behind the doors

?

## Example <br> The treasure behind the doors

- What shall the candidate do?
- Alter his decision?
- Retain his decision?
- Does it make a difference?

## Example <br> The treasure behind the doors

- What shall the candidate do?
- Alter his decision?
- Retain his decision?
- Does it make a difference?
- We will consider the solution to this Problem in some minutes

## Outline

(1) Introduction
(2) Notation
(3) Calculation with probabilities
(4) The Markov inequality
(5) The Chernoff bound

## Notation

## Experiments, Events and sample points

- The results of experiments or observations are called events.
- Events are sets of sample points.
- The sample space is the set of all possible events.

## Notation

## Experiments, Events and sample points

- What is the sample space for the experiment of tossing a coin two times?

## Example

## Sample spaces

- Three distinct balls (a,b,c) are to be placed in three distinct bins.

|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 2 3 | abc | abc | abc | $\begin{gathered} \hline \mathrm{ab} \\ \mathrm{c} \end{gathered}$ | ab <br> c | c ${ }_{\text {c }}$ | ab $c$ | c <br> ab | c | ac | ac <br> b | b | ac b |
| 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 |
| b ac | $\begin{gathered} \mathrm{b} \\ \mathrm{ac} \end{gathered}$ | $\begin{gathered} \mathrm{bc} \\ \mathrm{a} \end{gathered}$ | bc <br> a | a ${ }_{\text {b }}$ | bc a | a <br> bc | a bc | a | a c b | b | b c a | c | c |

## Example <br> Sample spaces

- Suppose that the three balls are not distinguishable.

| Event Bin | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | *** |  |  | ** | ** | * |  | * |  | * |
| 2 |  | *** |  | * |  | ** | ** |  | * | * |
| 3 |  |  | *** |  | * |  | * | ** | ** | * |

## Example

## Sample spaces

- Indistinguishable balls and indistinguishable bins

|  | Event | 1 | 2 | 3 |
| :--- | :--- | :---: | :---: | :---: |
| Bin |  |  |  |  |
| 1 |  | $* * *$ | $* *$ | $*$ |
| 2 |  |  | $*$ | $*$ |
| 3 |  |  |  | $*$ |

## Notation

## Probability space

A probability space ( $\Pi, P$ ) consists of a sample space $\Pi$ and a probability measure $P: \Pi \rightarrow[0,1]$. This function satisfies the following conditions

- For each subset $\Pi^{\prime} \subseteq \Pi, 0 \leq P\left(\Pi^{\prime}\right) \leq 1$
- $P(\Pi)=1$
- For each $\Pi^{\prime} \subseteq \Pi, P\left(\Pi^{\prime}\right)=\sum_{\chi \in \Pi^{\prime}} P(\chi)$

## Impossible events

## Impossible event

With $\chi=\{ \}$ we denote the fact that event $\chi$ contains no sample points. It is impossible to observe event $\chi$ as an outcome of the experiment.

## Probability of events

## Probability of events

Given a sample space $\Pi$ and an event $\chi \in \Pi$, the occurrence probability $P(\chi)$ of event $\chi$ is the sum probability of all sample points from $\chi$ :

$$
\begin{equation*}
P(\chi)=\sum_{x \in \chi} P(x) . \tag{1}
\end{equation*}
$$

## Statistical independence

## Independence

A collection of events $\chi_{i}$ that form the sample space $\Pi$ is independent if for all subsets $\Pi^{\prime} \subseteq \Pi$

$$
\begin{equation*}
P\left(\bigcap_{\chi_{i} \in \Pi^{\prime}} \chi_{i}\right)=\prod_{\chi_{i} \in S} P\left(\chi_{i}\right) . \tag{2}
\end{equation*}
$$

- Statistical independence is required for many useful results in probability theory.
- Be careful to apply such results not in cases where independence between sample points is not provided.

## Outline

(1) Introduction
(2) Notation
(3) Calculation with probabilities
(4) The Markov inequality
(5) The Chernoff bound

## Calculation with probabilities

## Negation of events

For every event $\chi$ there is an event $\neg \chi$ that is defined as ' $\chi$ does not occur'.

Negation of events
The event consisting of all sample points $x$ with $x \notin \chi$ is the complementary event (or negation) of $\chi$ and is denoted by $\neg \chi$.

## Calculation with probabilities

## Subsumming events

$$
\begin{align*}
& \chi_{1} \cap \chi_{2}=\left\{x \mid x \in \chi_{1} \wedge x \in \chi_{2}\right\}  \tag{3}\\
& \chi_{1} \cup \chi_{2}=\left\{x \mid x \in \chi_{1} \vee x \in \chi_{2}\right\} \tag{4}
\end{align*}
$$

## Calculation with probabilities

## Mutual exclusive events

Mutual exclusive events
When the events $\chi_{1}$ and $\chi_{2}$ have no sample point $x$ in common, the event $\chi_{1} \cap \chi_{2}$ is impossible: $\chi_{1} \cap \chi_{2}=\{ \}$. The events $\chi_{1}$ and $\chi_{2}$ are mutually exclusive.

## Calculation with probabilities

## Combining probabilities

- To compute the probability $P\left(\chi_{1} \cup \chi_{2}\right)$ that either $\chi_{1}$ or $\chi_{2}$ or both occur we add the occurrence probabilities

$$
\begin{equation*}
P\left(\chi_{1} \cup \chi_{2}\right) \leq P\left(\chi_{1}\right)+P\left(\chi_{2}\right) \tag{5}
\end{equation*}
$$

## Calculation with probabilities

## Combining probabilities

- To compute the probability $P\left(\chi_{1} \cup \chi_{2}\right)$ that either $\chi_{1}$ or $\chi_{2}$ or both occur we add the occurrence probabilities

$$
\begin{equation*}
P\left(\chi_{1} \cup \chi_{2}\right) \leq P\left(\chi_{1}\right)+P\left(\chi_{2}\right) \tag{5}
\end{equation*}
$$

- The ' $\leq$ '-relation is correct since sample points might be contained in both events:

$$
\begin{equation*}
P\left(\chi_{1} \cup \chi_{2}\right)=P\left(\chi_{1}\right)+P\left(\chi_{2}\right)-P\left(\chi_{1} \cap \chi_{2}\right) . \tag{6}
\end{equation*}
$$

## Example <br> Coin tosses

## Question

What is the probability that in two coin tosses either head occurs first or tail occurs second?

## Example <br> Coin tosses

| Events | coin tosses | probability |
| :--- | ---: | :--- |
| head - head |  |  |
| head - tail |  | $\frac{1}{2} \cdot \frac{1}{2}=\frac{1}{4}$ |
| tail - head |  | $\frac{1}{2} \cdot \frac{1}{2}=\frac{1}{4}$ |
| tail - tail |  | $\frac{1}{2} \cdot \frac{1}{2}=\frac{1}{4}$ |

## Example <br> Coin tosses

| Events | coin tosses | probability | sum probability |
| :--- | :--- | :--- | :--- |
| head - head | $\frac{1}{2} \cdot \frac{1}{2}=\frac{1}{4}$ |  |  |
| head - tail | $\frac{1}{2} \cdot \frac{1}{2}=\frac{1}{4}$ |  |  |
| tail - tail |  | $\frac{1}{2} \cdot \frac{1}{2}=\frac{1}{4}$ | $\frac{1}{4}+\frac{1}{4}+\frac{1}{4}=\frac{3}{4}$ |

## Calculation with probabilities

## Conditional probability

## Conditional probability

The conditional probability of two events $\chi_{1}$ and $\chi_{2}$ with $P\left(\chi_{2}\right)>0$ is denoted by $P\left(\chi_{1} \mid \chi_{2}\right)$ and is calculated by

$$
\begin{equation*}
\frac{P\left(\chi_{1} \cap \chi_{2}\right)}{P\left(\chi_{2}\right)} \tag{7}
\end{equation*}
$$

$P\left(\chi_{1} \mid \chi_{2}\right)$ describes the probability that event $\chi_{1}$ occurs in the presence of event $\chi_{2}$.

## Example

## Conditional probability

## Calculation with probabilities

## Bayes Rule

With rewriting and some simple algebra we obtain the Bayes rule:
Bayes Rule

$$
\begin{equation*}
P\left(\chi_{1} \mid \chi_{2}\right)=\frac{P\left(\chi_{2} \mid \chi_{1}\right) \cdot P\left(\chi_{1}\right)}{\sum_{i} P\left(\chi_{2} \mid \chi_{i}\right) \cdot P\left(\chi_{i}\right)} \tag{8}
\end{equation*}
$$

- This equation is useful in many statistical applications.
- With Bayes rule we can calculate $P\left(\chi_{1} \mid \chi_{2}\right)$ provided that we know $P\left(\chi_{2} \mid \chi_{1}\right)$ and $P\left(\chi_{1}\right)$.

## Calculation with probabilities

## Expectation

## Expectation

The expectation of an event $\chi$ is defined as

$$
\begin{equation*}
E[\chi]=\sum_{x \in \mathbb{R}} x \cdot P(\chi=x) \tag{9}
\end{equation*}
$$

## Example

## Expectation

## Example

Consider the event $\chi$ of throwing a dice. The Sample space is given by $S_{\chi}=\{1,2,3,4,5,6\}$.

What is the expectation of this event?

## Example

## Expectation

## Example

Consider the event $\chi$ of throwing a dice. The Sample space is given by $S_{\chi}=\{1,2,3,4,5,6\}$.

What is the expectation of this event?

- The expectation of this event is

$$
\begin{equation*}
E[\chi]=\frac{1}{6} \cdot(1+2+3+4+5+6)=3.5 \tag{10}
\end{equation*}
$$

## Calculation with probabilities

## Calculation with expectations

Linearity of expectation
For any two random variables $\chi_{1}$ and $\chi_{2}$,

$$
\begin{equation*}
E\left[\chi_{1}+\chi_{2}\right]=E\left[\chi_{1}\right]+E\left[\chi_{2}\right] . \tag{11}
\end{equation*}
$$

Multiplying expectations
For an independent random variables $\chi_{1}$ and $\chi_{2}$,

$$
\begin{equation*}
E\left[\chi_{1} \cdot \chi_{2}\right]=E\left[\chi_{1}\right] \cdot E\left[\chi_{2}\right] . \tag{12}
\end{equation*}
$$

## Calculation with probabilities

## Law of large numbers

Law of large numbers
Let $\{\bar{\chi}\}$ be a sequence of mutually independent random variables with a common distribution. If the expectation $E[\bar{\chi}]$ exists, then for every $\varepsilon>0$ and $n \rightarrow \infty$

$$
\begin{equation*}
P\left\{\left|\frac{\chi_{1}+\cdots+\chi_{n}}{n}-E[\bar{\chi}]\right|>\varepsilon\right\} \rightarrow 0 \tag{13}
\end{equation*}
$$

- Probability that the average value differs from expectation by less than $\varepsilon$ approaches one.

## Calculation with probabilities

## Variance

Variance
The variance of a random variable $\chi$ is defined as

$$
\begin{equation*}
\operatorname{var}[\chi]=E\left[(\chi-E[\chi])^{2}\right] . \tag{14}
\end{equation*}
$$

## Calculation with probabilities

## Calculation with variance

## Add variances

For any independent random variables $\chi_{1}$ and $\chi_{2}$

$$
\begin{equation*}
\operatorname{var}\left[\chi_{1}+\chi_{2}\right]=\operatorname{var}\left[\chi_{1}\right]+\operatorname{var}\left[\chi_{2}\right] . \tag{15}
\end{equation*}
$$

Multiplying variances
For any random variable $\chi$ and any $c \in \mathbb{R}$,

$$
\begin{equation*}
\operatorname{var}[c \chi]=c^{2} \operatorname{var}[\chi] \tag{16}
\end{equation*}
$$

## The Markov inequality

## Estimate the deviation of an event from its expectation

Markov inequality
Let $(\Pi, P)$ be a probability space and $x: \Pi \rightarrow \mathbb{R}^{+}$a non-negative random variable. For $t \in \mathbb{R}^{*}$ the following inequality holds:

$$
\begin{equation*}
P(x \geq t \cdot E[x]) \leq \frac{1}{t} \tag{17}
\end{equation*}
$$

## The Chernoff bound

## Estimate the deviation of an event from its expectation

## Chernoff bound

Let $(\Pi, P)$ be a probability space and $x_{1}, x_{2}, \ldots, x_{n}: \Pi \rightarrow\{0,1\}$ independent random variables with $0<P\left(x_{i}=1\right)<1$ for all $i \in\{1,2, \ldots, n\}$. For $X:=\sum_{1 \leq i \leq n} x_{i}$ and $\delta>0$ the following inequality holds:

$$
\begin{equation*}
P(X<(1+\delta) E[X])<\left(\frac{e^{\delta}}{(1+\delta)^{1+\delta}}\right)^{E[X]} \tag{18}
\end{equation*}
$$

and for all $\delta$ with $0<\delta<1$

$$
\begin{equation*}
P(X<(1-\delta) E[X])<e^{-\frac{E[X] \delta^{2}}{2}} \tag{19}
\end{equation*}
$$
